

# How to Horizontally Scale your .NET APIs

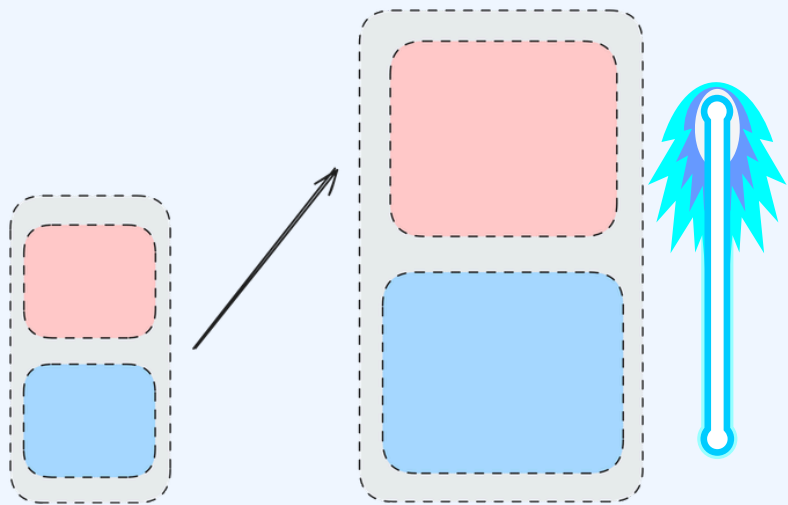

# Horizontal Scaling

## → More Performance

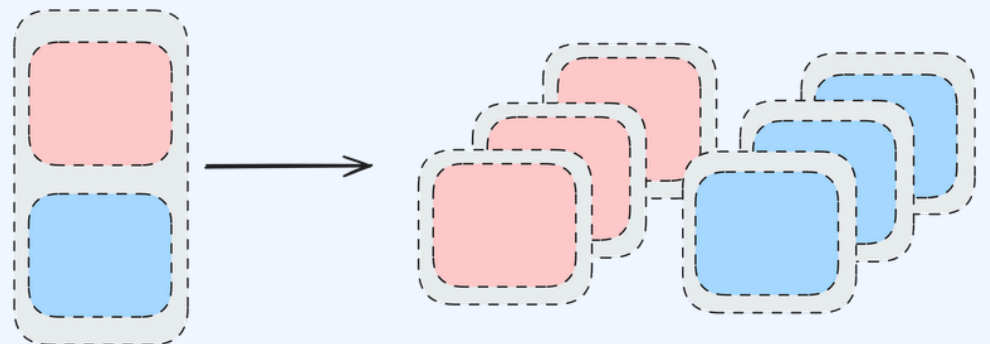

- 2x **FASTER** responses
- **+70% throughput** with YARP

### VERTICAL SCALING

### HORIZONTAL SCALING

# YARP for load balancing

Allows you to distribute requests easily

```
Install-Package Yarp.ReverseProxy
```

```
var builder = WebApplication.CreateBuilder(args);

builder.Services.AddReverseProxy()
    .LoadFromConfig(builder.Configuration.GetSection("ReverseProxy"));

var app = builder.Build();

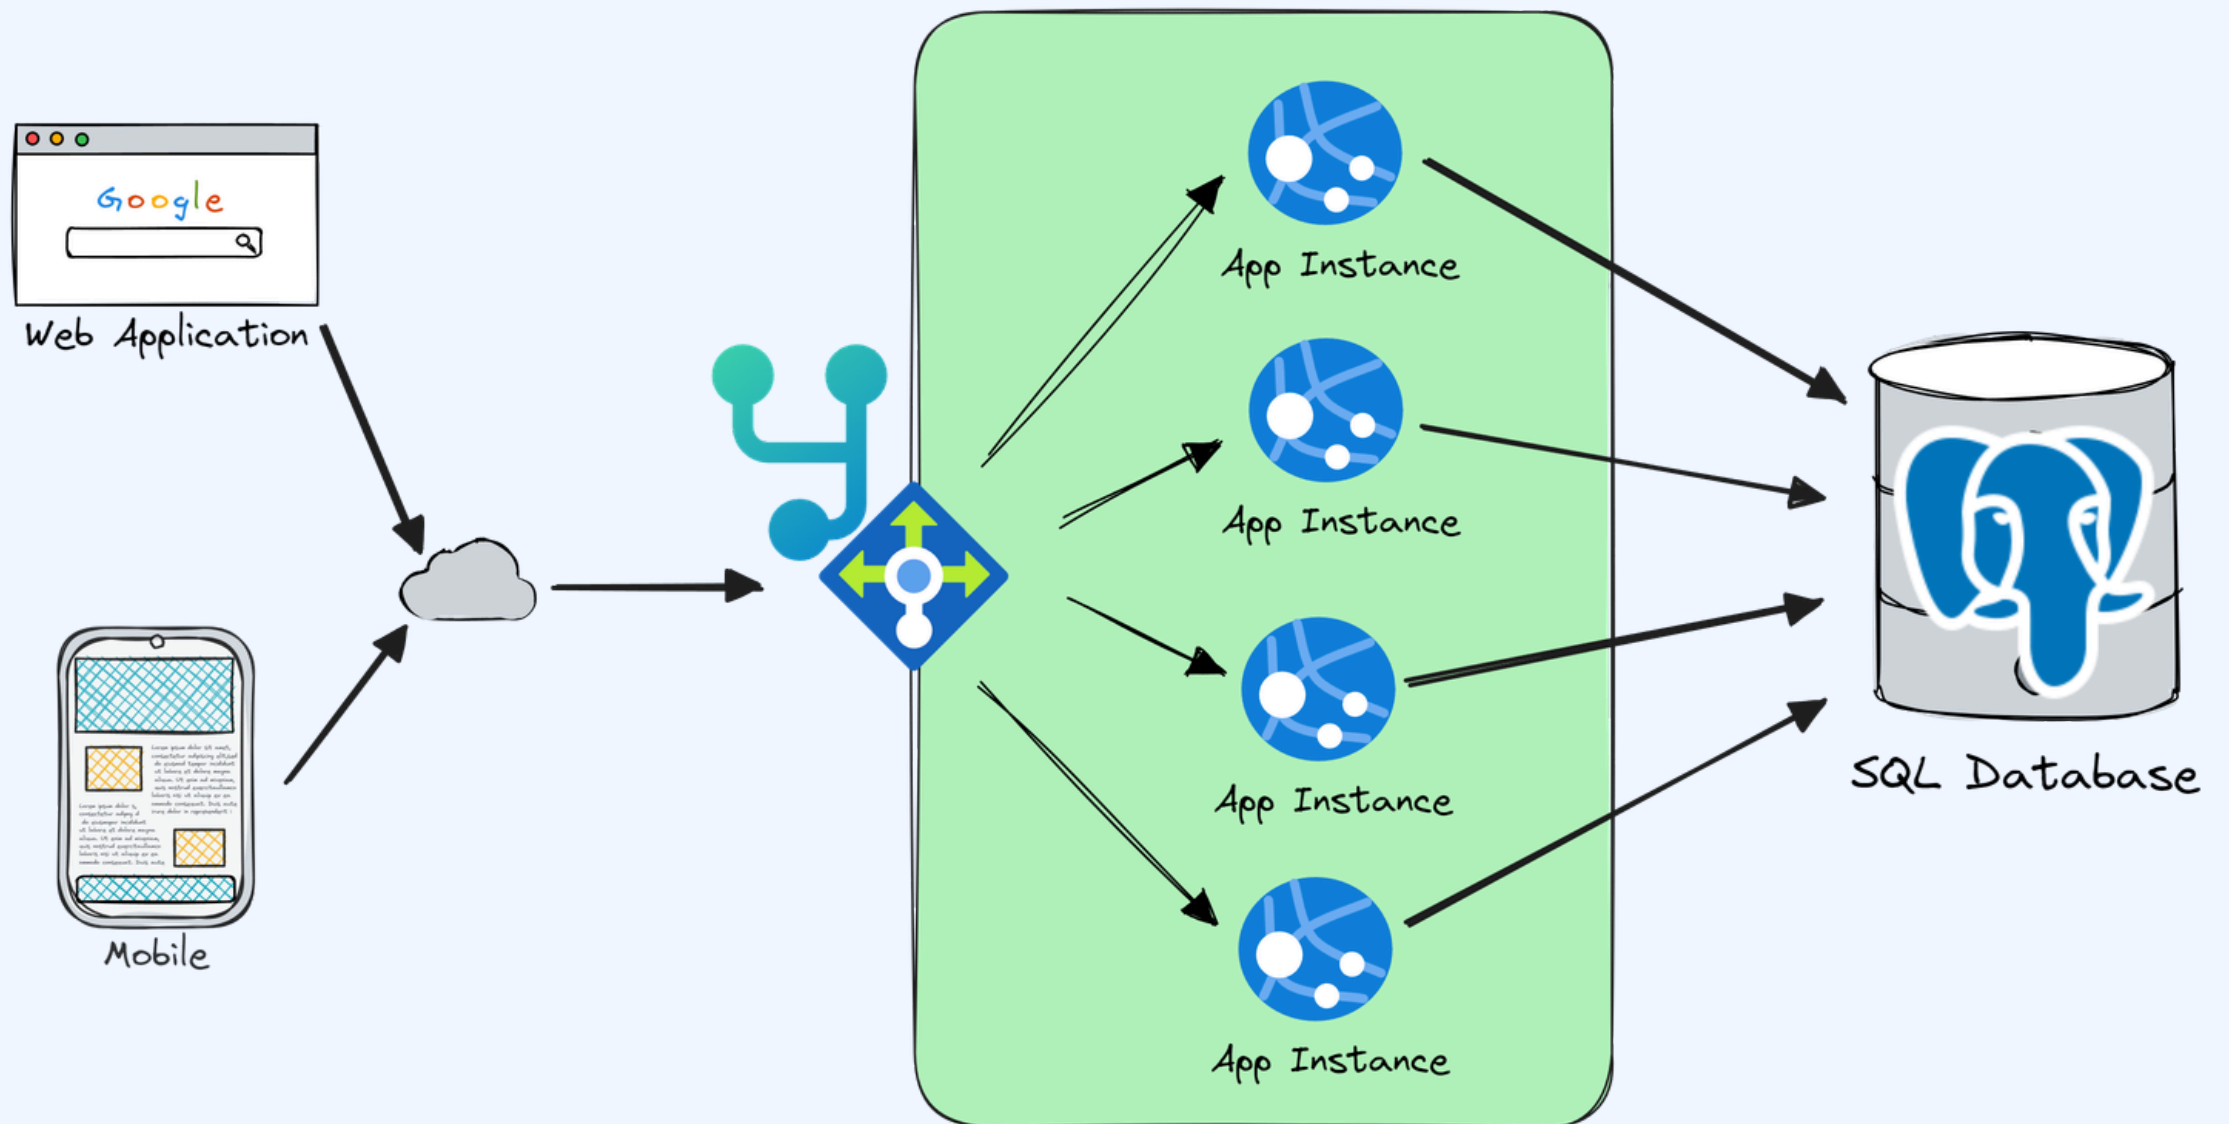

app.MapReverseProxy();

app.Run();
```

# Scaled out Architecture

The load balancer (proxy) accepts incoming requests

**The next problem you need to solve is how to design your application so it can scale horizontally. You need to think about concurrency and many other factors.**
